# TCP/IP ATTACKS DENIAL OF SERVICE

VITALY SHMATIKOV

# Warm Up: 802.11b

NAV (Network Allocation Vector)

- 15-bit field, max value: 32767
- Any node can reserve channel for NAV microseconds
- No one else should transmit during NAV period
  - ... but not followed by most 802.11b cards

De-authentication

- Any node can send deauth packet to AP
- Deauth packet unauthenticated
  - ... attacker can repeatedly deauth anyone

#### Pre HTTP/3

## Steps to Send an HTTP Request

- 1. DNS lookup on example.com to get IP address (1.2.3.4)
- 2. TCP connection setup via 4-way handshake of IP packets to and from 1.2.3.4
- 3. Send HTTP request over TCP connection

### Network Threat Models

## Internet Is a Network of Networks

- TCP/IP for packet routing and connections
- Border Gateway Protocol (BGP) for route discovery
- Domain Name System (DNS) for IP address discovery

### Internet Protocol Stack

HTTP, DNS, SMTP, SSH, etc. TCP, UDP IP, ICMP 802x (Ethernet, 802.11)

### IP: "The Narrow Waist"

#### Data Formats

## IP (Internet Protocol)

#### Connectionless

• Unreliable, "best-effort" protocol: no ordering, no retransmission, no error checking, no acknowledgement

Uses numeric addresses for routing

• Typically, several hops in the route

# IP Is Not Enough for Packet Delivery

Given an IP packet, how does the router know where to send it next?

On a local network, what MAC address corresponds to a given IP address?

ARP

BGP

### Global IPv4 Addresses

Class A network: owns all addresses with a given top byte Class B network: ... top 2 bytes Class C network: ... top 3 bytes

# Subnet Definition

#### IP address

Subnet part: high-order bitsHost part: low-order bits

#### What's a subnet ?

Device interfaces with the same subnet part of IP address
Can physically reach each other without an intervening router

# Subnetting Example

SubnetNumber	SubnetMask	NextHop	
128.96.34.0	255.255.255.128	Interface 0	
128.96.34.128	255.255.255.128	Interface 1	
128.96.33.0	255.255.255.0	R2	

#### Forwarding Algorithm

D = destination IP address for each entry <SubnetNum, SubnetMask, NextHop> D1 = SubnetMask & D if D1 = SubnetNum if NextHop is an interface deliver datagram directly to destination else deliver datagram to NextHop (a router)

## CIDR: Classless Inter-Domain Level Routing

CIDR balances two objectives: (1) minimize the number of routes that a router needs to know, and (2) hand out addresses efficiently

#### CIDR uses aggregate routes

- A single entry in the forwarding table tells the router how to reach a lot of different networks
- No rigid boundaries between address classes
- Variable number of bits per aggregated ranges of addresses

### Classless Addressing

Network number may be of any length Represent network number with a single <length, value> pair

### Classless Address Block Management

AS with 16 class-C networks: instead of handing out 16 class-C addresses at random, hand out a block of class-C addresses that share a common prefix

- E.g., class-C network numbers from 192.4.16 through 192.4.31, so the top 20 bits of all addresses in this range are the same (11000000 00000100 0001)
- This implicitly creates a 20-bit network number
- Prefix convention: /X after prefix, where X is prefix length in bits
  - 20-bit prefix for 192.4.16 through 192.4.31: 192.4.16/20
  - A single class-C network number, 24 bits long: 192.4.16/24

# IP Forwarding w/ Longest Match

#### Router tables may have prefixes that overlap

- Some addresses may match more than one prefix
- Both 171.69 (a 16-bit prefix) and 171.69.10 (a 24-bit prefix) in the forwarding table of a single router
- Packet destined to 171.69.10.5 matches both prefixes

Matching is based on the principle of "longest match"

• 171.69.10 in the above case

A packet destined to 171.69.20.5 would match to 171.69 and not 171.69.10

# Longest Prefix Matching

When looking for forwarding table entry for given destination address, use longest (ie, most specific) address prefix that matches destination address

Destination Address Range	Link interface
11001000 00010111 00010*** *******	0
11001000 00010111 00011000 *******	1
11001000 00010111 00011*** *******	2
otherwise	3

DA: 11001000000101110001011010100001which interface?DA: 11001000000101110001100010101010which interface?

### Transport Protocols

Goal: provide logical end-to-end communication channel between app processes running on different hosts • Examples: TCP and UDP

## TCP (Transmission Control Protocol)

Sender: break data into packets, attach **sequence number** to every packet Receiver: reassemble packets in correct order • Acknowledge receipt; lost packets are re-sent

Connection state maintained on both sides

# User Datagram Protocol (UDP)

#### UDP is a connectionless protocol

- Simply send datagram to application process at the specified port of the IP address
- Source port number provides return address
- Applications: media streaming, broadcast

No acknowledgement, no flow control, no message continuation

# ICMP (Control Message Protocol)

Provides feedback about network operation

• "Out-of-band" messages carried in IP packets

Error reporting, congestion control, reachability...

- Destination unreachable
- Time exceeded
- Parameter problem
- Redirect to better gateway
- Reachability test (echo / echo reply)
- Message transit delay (timestamp request / reply)

## The Internet Was Designed in the 1970s...

All transmissions are in the clear • Eavesdropping Nothing is authenticated or integrity-protected • Spoofing, packet injection, etc. Anyone can freely talk to anyone • Denial of service

Image: Forbes

# Packet Sniffing

Network interface card (NIC) in "promiscuous mode" reads all passing data Many applications send data unencrypted

# TCP/IP Implementation Bugs

"Ping of Death"

 Old versions of Windows would crash if ICMP packet has payload longer than 64K (illegal per protocol RFC)

#### "Teardrop" and "Bonk"

 Bad implementations of TCP/IP crash if Offset fields in TCP fragments are set to large or overlapping values

#### "Land"

 IP packet with source address, port equal to destination address, port and SYN flag set triggers loopback in the Windows XP SP2 implementation of TCP/IP stack, locks up CPU

Solution: use up-to-date TCP/IP implementation, ingress filtering

Common cause: implementors assume that input will follow specification ... but attackers can and will send malformed inputs

#### IP header

### TCP Handshake

### Low-Rate SYN Floods

OS	Backlog queue size
Linux 1.2.x	10
FreeBSD 2.1.5	128
WinNT 4.0	6

Backlog timeout: 3 minutes

Attacker need only send 128 SYN packets every 3 minutes

Phrack 48, no 13, 1996

# SYN Flooding Explained

Attacker sends many connection requests with spoofed source addresses

Victim allocates resources for each request

New thread, connection state maintained until timeout

• Fixed bound on half-open connections

Once resources exhausted, requests from legitimate clients are denied

This is a classic denial of service pattern: it costs nothing to TCP initiator to send a connection request, but TCP responder must spawn a thread for each request - asymmetry!

# Preventing SYN Floods

DoS is caused by asymmetric state allocation

• If responder opens new state for each connection attempt, attacker can initiate thousands of connections from bogus or spoofed IP addresses

Cookies ensure that the responder is stateless until initiator produced at least two messages

- Responder's state (IP addresses and ports of the connection) is stored in a cookie and sent to initiator
- After initiator responds, cookie is regenerated and compared with the cookie returned by the initiator

http://cr.yp.to/syncookies.html

# Anti-Spoofing Cookies: Basic Pattern

Client sends request (message #1) to server

- Typical protocol:
  - Server sets up connection, responds with message #2
  - Client may complete session or not potential DoS!

Cookie version:

- Server responds with hashed connection data instead of message #2
- Client confirms by returning hashed data
- Need an extra step to send postponed message #2, <u>except</u> in TCP (can piggyback on SYN-ACK in TCP)

If source IP address is spoofed, attacker can't confirm

# Another Defense: Random Deletion

SYNC

If SYN queue is full, delete random entry

- Legitimate connections have a chance to complete
- Fake addresses will be eventually deleted

Easy to implement

half-open connections

121.17.182.45

231.202.1.16

121.100.20.14

5.17.95.155

# Prolexic, Google Project Shield, etc.

Idea: only forward established TCP connections to site

Prolexic purchased by Akamai in 2014 Many companies: Cloudflare, Imperva, Arbor Networks, ...

# Other Junk-Packet Attacks

Proxy must keep floods of these away from website

Attack Packet	Victim Response	Rate: attk/day [ATLAS 2013]
TCP SYN to open port	TCP SYN/ACK	773
TCP SYN to closed port	TCP RST	
TCP ACK or TCP DATA	TCP RST	
TCP RST	No response	
TCP NULL	TCP RST	
ICMP ECHO Request	ICMP ECHO Response	50
UDP to closed port	ICMP Port unreachable	387

# Ingress Filtering

Attacker's goal: prevent legitimate users from accessing victim (1.2.3.4)

ICMP ping flood

- Attacker sends ICMP pings as fast as possible to victim
- When will this work as a DoS? Attacker resources > victim's
- How can this be prevented?

Ingress filtering of attacker IP addresses near victim once attack identified

### Predictable Sequence Numbers

BSD 4.4 used predictable initial sequence numbers (ISNs)

- At system initialization, set ISN to 1
- Increment ISN by 64,000 every half-second

What can a clever attacker do? (assume spoofing possible)

# TCP Spoofing

Each TCP connection has associated state • Sequence number, port number TCP state is easy to guess

• Port numbers standard, seq numbers predictable

#### Can inject packets into existing connections

- If attacker knows the initial sequence number and amount of traffic, can guess likely current number
- Guessing a 32-bit seq number is not practical, but most systems accept large windows of sequence numbers (to handle packet losses), so send a flood of packets with likely sequence numbers

(remote shell, SPF defense against spam)

# How to Fix Predictable Seq Numbers

Fix idea 1:

8.7.3.4

- Random ISN at system startup
- Increment by 64,000 each half second

Better fix:

SYN cookies ensure this

- Random ISN for every connection  $\leftarrow$ 

Remains an issue in some cases:

- Any FIN accepted with seq number in receiver window: 2<sup>17</sup> attempts
- Side-channel attacks to infer seq number

# Avoiding Ingress Filtering

- 1. Attacker can send packet with fake ("spoofed") source IP address. Packet will get routed correctly. Replies will not.
- 2. Distribute attack across many IP addresses

IP traceback: techniques for inferring actual source of a (spoofed) packet
BCP 38 (RFC 2827): upstream ingress filtering to drop spoofed packets
Ideally, all network traffic providers would perform ingress filtering... but they don't

#### https://spoofer.caida.org/summary.php

#### Digital Attack Map Top daily DDoS attacks worldwide

# TCP Con Flood

Command a bot/zombie army to: Complete TCP connection to web site • Send short HTTP HEAD request • Repeat Will bypass SYN flood protection proxy but attacker cannot use spoofed source IPs Reveals location of bot zombies Proxy can now block or rate-limit bots

### DDoS Attack on Estonia

April 27, 2007

Continued for weeks, with varying levels of intensity Government, banking, news, university websites Government shut down international Internet connections

# Telegram blames China for 'powerful DDoS attack' during Hong Kong protests

Telegram CEO says 'IP addresses coming mostly from China' were to blame

By Jon Porter | @JonPorty | Jun 13, 2019, 4:21am EDT

### Mirai Botnet

Origin: game-booting code from Lizard Squad

• Used in attacks on Sony PlayStation and Xbox Live networks

Scans big blocks of Internet address space for open telnet ports, logs in using default passwords **K** 

Assembled an army of 1 to 2.5 million IoT devices

In 2016, used to stage massive DDoS attacks on DYN's DNS servers Knocked out access to 1200 websites, including Twitter, Netflix, Paypal, Shopify, GitHub...

Much more about DNS later

image: vice.com

# Amplification

Key element of many powerful DoS attacks Achieves attacker resources >>> victim's

- 1 request sent by attacker => N requests received by the victim
- 1 byte sent by attacker => N bytes received by the victim (N can be 200+ in some attacks)

Force victim to expend computation, logical resources

# "Smurf" Reflector Attack

# NTP Reflection + Amplification

December 2013 – February 2014: 400 Gbps DDoS attacks involving 4,529 NTP servers

7 million unsecured NTP servers on the Internet (Arbor)

### UDP in Reflection Attacks

DNS, memcached, ... application-layer protocols running on UDP are often exploited in DoS attacks

Single packet to victim service yields response, so spoofing + reflection works

	IP hdr	UDP hdr	data	
16-bit			16-bit	
source port n	umber		destination port r	lumber
16-bit		16-bit		
UDP length			UDP checksu	Im

length = header len + data len

# Memcached DDoS Attacks

Memcached is a popular in-memory data store Supports UDP requests Default configuration: accept UDP requests from anywhere Standard reflector attack • Insert data into the Memcached server • Send UDP requests with source IP addr of victim

# DDoS Attack on GitHub (Feb 2018)

• **51,000x** bandwidth amplification

1.3 TB/s of traffic to GitHub from 1000+ ASes

• GitHub offline for 5 minutes

• Response

Use BGP announcement to route GitHub traffic through Akamai
Akamai gives more capacity + helps filter out bogus requests

• Turn off UDP support in Memcached (now off by default)

https://github.blog/2018-03-01-ddos-incident-report/

#### Largest European DDoS Attack on Record

Craig Sparling July 27, 2022

#### "

On Thursday, July 21, 2022, Akamai detected and mitigated the largest DDoS attack ever launched against a European customer on the Prolexic platform. Victim: an Akamai customer in Eastern Europe

Source: a highly-sophisticated, global botnet of compromised devices

75 attacks over 30 days using UDP, UDP fragmentation, ICMP flood, RESET flood, SYN flood, TCP anomaly, TCP fragment, PSH ACK flood, FIN push flood, and PUSH flood. **UDP most popular.** 

Peak rates: 854 Gbps and 660M packets/sec

Same customer attacked again on Sep 22: 705M packets/sec

https://www.akamai.com/blog/security/largest-european-ddos-attack-ever

### Security News This Week: The Biggest DDoS Attack in History Hit Russian Tech Giant Yandex

Wired (September 11, 2021)

A massive botnet, dubbed Mēris, is believed responsible, flooding Yandex with millions of HTTP requests for webpages at the same time.

This DDoS technique is called HTTP pipelining, where a browser requests a connection to a server and, without waiting for a response, sends multiple more requests. Those requests reportedly originated from networking gear made by MikroTik. Attackers, according to Qrator Labs, exploited a 2018 bug unpatched in more than 56,000 MikroTik hosts involved in the DDoS attack.

The Mēris botnet delivered the largest attack against Yandex it has ever spotted (by traffic volume) – peaking at 21.8 million requests per second (RPS).

https://threatpost.com/yandex-meris-botnet/169368/

# Record DDoS Attack with 25.3 Billion Requests Abused HTTP/2 Multiplexing

June 27, 2022

Target: a Chinese telecom company

Method: HTTP/2 multiplexing (multiple packets in one) from a botnet of 170,000 different routers, security cameras, compromised servers in over 180 countries

Peak rate: 3.9 million requests per second

https://thehackernews.com/2022/09/record-ddos-attack-with-253-billion.html
